Abstract A new chigger mite species, *Schoutedenichia microcebi* n. sp. is described from the grey mouse lemur *Microcebus murinus* (J.F. Miller) from Madagascar. The new species is closely related to *S. dutoiti* (Radford, 1948), a species described from a single specimen collected on a rodent in South Africa. Examination of the holotype and new material on *S. dutoiti* from South Africa enabled us to re-describe this species and provide new data on its hosts and geographical distribution.

Introduction

There are currently nine known species of chigger mites in Madagascar, of which only one, *Trisetica aethiopica* (Hirst, 1926), has also been found on the African continent. However, most Madagascan chigger species have close relatives in Africa (Stekolnikov & Fain, 2004; Stekolnikov, 2018). A rather large sample of ectoparasites collected from 107 grey mouse lemurs *Microcebus murinus* (J. F. Miller) in Ankarafantsika National Park by S. E. Kessler and A. F. Hasiniaina included one chigger mite species belonging to the genus *Schoutedenichia* Jadin & Vercammen-Grandjean, 1954. *Schoutedenichia* is a genus belonging to the tribe Schoengastiini which has a worldwide distribution. The last checklist of the Trombiculinae prepared by Vercammen-Grandjean (1965) included 61 species of *Schoutedenichia*, 46 of which were described from the Afrotropical zoogeographical region. Later, many new species were described from Africa (Stekolnikov, 2018), Australia (Domrow & Lester, 1985), India (Fernandes & Kulkarni, 2003), Iran (Stekolnikov et al., 2019), and other regions of the world. Examination of the last revision of this genus (Vercammen-Grandjean, 1958) and all descriptions of its species published later led us to the conclusion that our material belongs to a new species, which is closely related to a little known South African species, *Schoutedenichia dutoiti* (Radford, 1948). Fortunately, the first author had the opportunity to examine the holotype of *S. dutoiti* held in the Natural History Museum (NHM, London, UK). Moreover, a large sample of *S. dutoiti* was collected from rodents in the Mpumalanga Province of South Africa by S. Matthee and identified by the first author that allowed a reliable morphological comparison of the new species with *S. dutoiti*.

Materials and methods

All specimens of the new mite species (parasitic larvae) were collected from wild grey mouse lemurs in Ankarafantsika National Park near the Ampijoroa forestry station (16°19'S, 46°48'E) in Jardin Botanique A (JBA), Madagascar. In total, 107 grey mouse lemurs were trapped in Sherman live traps (H. B. Sherman Traps, Inc., Tallahassee, FL, USA) baited with banana during the dry season (May through November) of 2010 and 2011. Lemurs were removed from traps, restrained by hand, and examined for ectoparasites. We inspected the face, ears, and tail, then parted the fur on the back and legs. Ectoparasites were preserved in 90% ethanol. Lemurs were fed banana and released at their capture sites at dusk (for details see Kessler et al., 2014, 2018).

New specimens of *S. dutoiti* were collected from rodents by S. Matthee, as reported by Stekolnikov & Matthee (2019).

Preparation of the new material was completed by V. A. Stekolnikova (specimens of *Schoutedenichia microcebi* n. sp.) and A. A. Stekolnikov (specimens of *S. dutoiti*) in the Laboratory of Parasitic Arthropods, Zoological Institute of the Russian Academy of Sciences (ZIN, Saint Petersburg, Russia). Specimens were slide-mounted using Faure-Berlese medium (de Faure's medium), according to standard methodologies (Krantz, 1978). Identification was carried out by A. A. Stekolnikov with the use of a MBI-3 microscope (LOMO plc, St. Petersburg, Russia) with phase contrast optics. Measurements were made with an ocular micrometer; drawings were prepared using a drawing tube. Microphotographs were taken using a Leica DM5000B microscope (Leica Microsystems GmbH, Wetzlar, Germany) connected to a TouPCam 5.1 digital camera, model FMA050 (Hangzhou ToupTek Photonics Co., Ltd, Hangzhou, Zhejiang, China) using differential interference contrast.

The holotype of *S. dutoiti* was examined by A. A. Stekolnikov during his visit to the Natural History Museum, London, in November 2017. The arrangement of the idiosomal setae of this species was drawn using an Olympus BH-2 microscope (Olympus Corporation, Tokyo, Japan) with a camera lucida; measurements were performed using a Zeiss Axiophot microscope (Carl Zeiss AG, Oberkochen, Germany) with an ocular micrometer.

For the description, we have used the standard terminology, abbreviations and diagnostic formulae generally accepted in the taxonomy of trombiculids (Goff et al., 1982, Stekolnikov, 2018). All measurements are given in micrometres. Intervals of variation are bracketed in the formulae for the arrangement of dorsal idiosomal setae (fD); square brackets mark the first (double) row; plus signs separate the total number of caudal setae which cannot be unambiguously divided into rows. In the schemes of the dorsal idiosomal setae arrangement, dotted lines outline tentative boundaries between rows of setae. The double circles in the figures

of the legs represent the bases of unspecialised tactile setae; single circles correspond to the unspecialised setae situated on the opposite side of the leg.

The holotype of the new species, as well as the additional material of *S. dutoiti*, is deposited in the Zoological Institute of the Russian Academy of Sciences, Saint Petersburg, Russia (ZIN); paratypes will be deposited in ZIN and the Natural History Museum, London, UK (NHM).

***Schoutedenichia (Schoutedenichia) microcebi* Stekolnikov n. sp.**

Type-host: Microcebus murinus (J.F. Miller) (Primates: Cheirogaleidae), grey mouse lemur.

Type material: Larval holotype (ZIN, 11007, T-Tr.-85) ex *Microcebus murinus*, female No. 04-11, sample 120 5/3, Madagascar, Boeny Region, Ankarafantsika National Park, Jardin Botanique A, 14.viii.2011, collected by S.E. Kessler and A.F. Hasiniaina; 71 larval paratypes (ZIN, 10987–11057) ex 12 specimens of *M. murinus*, same locality, 11.vi.2011 and 13.vi.2011, 22.vii.2011 and 26.vii.2011, 14.viii.2011 and 16.viii.2011, collected by S. E. Kessler and A. F. Hasiniaina.

ZooBank registration: The Life Science Identifier (LSID) for *Schoutedenichia (Schoutedenichia) microcebi* n. sp. is urn:lsid:zoobank.org:act:17FE3F94-9F3A-45D1-9222-F1274A468C4E.

Etymology: The new species name refers to the host genus.

Description (Figs 1–14)

Larva [Based on the holotype and 11 paratypes (nos 10991, 10997, 10998, 11001/1, 11022, 11026, 11032, 11044, 11049, 11054, 11055); measurements are given in Table 1.] Idiosoma (Figs. 2–5, 8, 9). Eyes 2 + 2. Two pairs of humeral setae and 38–44 moderately barbed dorsal idiosomal setae; always 8 (6 + 2) setae in 1st row, 10 setae in 2nd row, and 8 setae in 3rd row; 6 setae in 4th row in 6 specimens and 4 setae in 4 specimens; distribution of caudal setae by rows is uncertain; formula of humeral and dorsal idiosomal setae of holotype fD = 4H-[6-2]-10-8-6-4-4-2-2; 4 sternal setae; 32–40 ventral setae; total number of idiosomal setae (NDV), excluding coxal and sternal, 75–83.

Gnathosoma (Figs. 6, 7, 11). Cheliceral blade with tricuspid cap; proximal half of cheliceral base with small puncta; gnathobase bears one pair of branched setae; galeal setae nude; palpal claw with 3 prongs (Fig. 11); palpal femoral and genual setae with long branches; dorsal and lateral palpal tibial setae nude, ventral palpal tibial seta branched; palpal tarsus with 4 branched setae, nude subterminala, and basal tarsala.

Scutum (Figs. 1, 8, 10). Nearly trapezoidal, wider than long, with sinuous anterior margin and deeply bilobate posterior margin, with small, rather sparse puncta and irregular cracks in all specimens examined; AM at level of ALs; sensillary bases slightly anterior to level of PLs (PSB – P-PL = 3–7); PL > AL > AM; AM and ALs with long thin barbs, PLs barbed similar to dorsal idiosomal setae; sensilla nearly globose, covered with pointed scales.

Legs (Figs. 12–14). All legs 7-segmented, with 1 pair of claws and claw-like empodium. Leg I: coxa with 1 non-specialised branched seta (1B); trochanter 1B; basifemur 1B; telofemur 5B; genu 4B, 2 genualae, microgenuala; tibia 8B, 2 tibialae, microtibiala; tarsus 22B, tarsala, microtarsala at level of tarsala, subterminala, parasubterminala, pretarsala. Leg II: coxa 1B; trochanter 1B; basifemur 2B; telofemur 4B; genu 3B, genuala; tibia 6B, 2 tibialae; tarsus 16B, tarsala, microtarsala at level of tarsala, pretarsala. Leg III: coxa 1B; trochanter 1B; basifemur 2B; telofemur 3B; genu 3B, genuala; tibia 6B; tarsus 15B.

Diagnosis

SIF = 4BS-N-3-2110.0000; fsp = 7.7.7; fCx = 1.1.1; fSt = 2.2; fPp = B/B/NNB; fSc: PL > AL > AM; Ip = 609–664; fD = 4H-[6-2]-10-8-6(4)+(6–12); DS = 42–48; VS = 32–40; NDV = 75–83.

Differential diagnosis

The new species is similar to *Schoutedenichia dutoiti* (Radford, 1948) and differs from it in having fewer idiosomal setae (DS = 42–48, VS = 32–40, and NDV = 75–83 vs 70–94, 55–76, and 135–166, respectively); fD = 4H-[6-2]-10-8-6(4)+(6–12) vs 4H-[8(9)-4(5)]-(15–18)-(10–13)+(19–30); a shorter scutum (ASB = 19–22 µm; PSB = 12–15 µm; SD = 33–37 µm; and AP = 23–26 vs 28–31 µm, 20–23 µm, 49–53 µm, and 37–41 µm, respectively); in having deeply bilobate posterior scutal margin vs slightly bilobate; in having sensillary bases situated slightly anterior to level of PLs vs far anterior (PSB–P-PL = 3–7 vs 13–16 µm); in AL ≥ PL vs PL > AL; in having long thin barbs of AM and ALs vs AM and ALs barbed similar to PLs and dorsal idiosomal setae; in the absence of additional hook of cheliceral blade; in the absence of puncta on gnathobase and palpal femur; and in having shorter legs (Ip = 609–664 vs 792–846 µm).

The new species differs from the three species of *Schoutedenichia* (*Schoutedenichia*) previously described in Madagascar, as follows: (i) from *S. gigantea* Vercammen-Grandjean & Watkins, 1965 and *S. tiptoni* Vercammen-Grandjean & Watkins, 1965: by its smaller size (e.g. Ip = 609–664 µm in *S. microcebi*, 1,400 µm in *S. gigantea*, and 992 µm in *S. tiptoni*; PW = 64–80 µm in *S. microcebi*, 119 µm in *S. gigantea* and 107 µm in *S. tiptoni*; PL = 36–41 µm in *S.*

microcebi, 137 μm in *S. gigantea*, and 88 μm in *S. tiptoni*); in having fewer idiosomal setae (NDV = 75–83 vs 140 in *S. gigantea* and 194 in *S. tiptoni*), and in the presence of usual two posterior sternal setae vs 10 (6 + 4) (Vercammen-Grandjean & Watkins, 1965). The new species also differs from *S. gigantea* by the absence of large hooks of helicer blades and from *S. tiptoni* by the presence of one seta on coxa III vs 3–4 setae; (ii) from *S. subterranea* Stekolnikov & Fain, 2004: by the presence of bilobate posterior margin of the scutum vs concave; different proportions of the scutum (AP = 23–26 vs 40); normally developed eyes vs nearly reduced; heavily barbed idiosomal setae vs having a few short barbs in *S. subterranea*; in having longer scutal setae (AM = 22–27 μm , AL = 30–36 μm and PL = 36–41 vs 16–18 μm , 16–22 μm and 29–30 μm , respectively); and in having fewer idiosomal setae (NDV = 75–83 vs 102–107).

Schoutedenichia (Schoutedenichia) dutoiti (Radford, 1948)

Syns *Ascoshöngastia dutoiti* Radford, 1948; *Euschöngastia dutoiti* of Wharton & Fuller (1952)

Hosts: Saccostomus campestris Peters (Rodentia: Nesomyidae) (Radford 1948). *Aethomys ineptus* (Thomas & Wroughton), *Gerbilliscus leucogaster* (Peters), *Mastomys natalensis* Smith, and *Rattus tanezumi* Temminck (Rodentia: Muridae) (present study).

Type-material examined: Larval holotype (NHM 1948.2.3.30; labeled as “lectotype” by the hand of Radford) ex *Saccostomus campestris*, Albany, C[ape] P[rovince], Palmers Dam (unknown locality in the Western Cape Province of South Africa), 23 April [19]39, [Collector] Dr. G. Theiler.

Additional material examined: 44 larvae (ZIN 9968–10390) from South Africa, Mpumalanga Province, collector S. Mathee: 9 larvae from ears of two *A. ineptus* (MNRAeth2 and MNRTI6), Manyeleti Nature Reserve (24°38'52"S, 31°31'35"E), ix.2015; 7 larvae from edge of ear lobe of *G. leucogaster* (ThT11), Hlavekisa village (24°37'51"S, 31°22'42"E), ix.2015; 17 larvae from edge of ear lobe of five *M. natalensis* (GbGMas13, GbGMas14, GbGMas15, GbGMas17, GbgMas9), Gottenburg village (24°38'01"S, 31°25'19"E), ix.2015; 3 larvae from ear lobe of *M. natalensis* (HlvMas3), Hlavekisa, ix.2015; 8 larvae from edge of ear lobe of *R. tanezumi* (GbGMas16), Gottenburg, ix.2015.

Distribution: South Africa: Western Cape Province and Mpumalanga Province (present study).

Redescription (Figs. 15–31)

Larva [Based on the holotype and 8 specimens from the additional material (nos 9971, 9973–9975, 10215, 10387, 10389, 10214 - figure of cheliceral blades only); metrical data are given in Table 1.] Idiosoma (Figs. 16–20, 24, 25). Eyes 2 + 2. Two pairs of humeral setae and 70–94 moderately barbed dorsal idiosomal setae; 12–14 setae in 1st row, 15–18 setae in 2nd row, and 10–13 setae in 3rd row; distribution of posterior 19–30 setae by rows is uncertain; formula of humeral and dorsal idiosomal setae of holotype $fD = 4H-[8-4]-14-12-11+17$; 4 sternal setae; 55–76 ventral setae; total number of idiosomal setae (NDV), excluding coxal and sternal, 135–166.

Gnathosoma (Figs. 21–23). Cheliceral blade with tricuspid cap and additional hook (Fig. 23); proximal half of cheliceral base with large puncta; gnathobase and palpal femur with puncta; gnathobase bearing one pair of branched setae; galeal setae nude; palpal claw with 3 prongs; palpal femoral and genual setae with long branches; dorsal and lateral palpal tibial setae nude, ventral palpal tibial seta with few long branches; palpal tarsus with 4 branched setae, nude subterminala, and basal tarsala.

Scutum (Figs. 15, 24, 26). Nearly trapezoidal, wider than long, with sinuous anterior margin and slightly bilobate posterior margin, with small puncta; AM at level of ALs; sensillary bases far anterior to level of PLs ($PSB - P-PL = 13-16$); $AL \geq PL > AM$; all scutal setae barbed similar to dorsal idiosomal setae; sensilla nearly globose, covered with pointed scales.

Legs (Figs. 27–31). All legs 7-segmented, with 1 pair of claws and claw-like empodium. Leg I: coxa with 1 non-specialised branched seta (1B); trochanter 1B; basifemur 1B; telofemur 5B; genu 4B, 2 genualae, microgenuala; tibia 8B, 2 tibialae, microtibiala; tarsus 22B, tarsala, microtarsala slightly posterior to tarsala, subterminala, parasubterminala, pretarsala. Leg II: coxa 1B; trochanter 1B; basifemur 2B; telofemur 4B; genu 3B, genuala; tibia 6B, 2 tibialae; tarsus 16B, tarsala, microtarsala posterior to tarsala, pretarsala. Leg III: coxa 1B; trochanter 1B; basifemur 2B; telofemur 3B; genu 3B, genuala; tibia 6B; tarsus 15B.

Diagnosis

SIF = 4BS-N-3-2110.0000; $f_{sp} = 7.7.7$; $f_{Cx} = 1.1.1$; $f_{St} = 2.2$; $f_{Pp} = B/B/NNB$; f_{Sc} : $AL \geq PL > AM$; $I_p = 792-846$; $fD = 4H-[8(9)-4(5)]-(15-18)-(10-13)+(19-30)$; $DS = 70-94$; $VS = 55-76$; $NDV = 135-166$.

Remarks

This species was described from a single specimen. Vercammen-Grandjean (1958), in his revision of the genus *Schoutedenichia*, reproduced data from the original description of *S. dutoiti*. He did not see the holotype, but prepared new drawings, which were based on the

illustrations made by Radford (1948). He also gave the exact numbers of dorsal and ventral idiosomal setae, obviously, on the base of an examination of the figure in the original description. There are 88 setae in the dorsal view of the idiosoma, including humeral setae, and 74 setae in the ventral view, excluding sternal and coxal setae (figures 11–12 in Radford, 1948). According to Vercammen-Grandjean (1958), fD = 88 and fV = 70; presumably, he assumed that 4 caudal setae were depicted by Radford twice, in dorsal and ventral views. The numbers of setae given in the original description are approximate: “about ninety” and “about seventy-six” Radford (1948, p. 218). According to our examination of the holotype, DS is 70 and VS is 65 in this specimen.

Discussion

Schoutedenichia microcebi n. sp. is the fourth species of *Schoutedenichia* recorded from Madagascar, after *S. gigantea*, *S. tiptoni* and *S. subterranea*. However, this represents the first chigger species found parasitising lemurs in Madagascar: previously known Madagascan chiggers were collected from species of Rodentia, Afrosoricida, Anura and Squamata. Generally, records of *Schoutedenichia* from primates are few: two species, *S. evansi* Vercammen-Grandjean, 1958 and *S. zanzibarica* Vercammen-Grandjean, 1958, were described from *Galago senegalensis* É. Geoffroy in Tanzania and *S. potto* Vercammen-Grandjean & Yang, 1964 was described from *Perodicticus potto ibeanus* Thomas in the Democratic Republic of the Congo (Stekolnikov, 2018). Thus, all known primate hosts of *Schoutedenichia* belong to the same suborder, Strepsirrhini, which includes lemuriform and loriform primates from Madagascar, Africa, India and Southeast Asia.

A recently published survey of ectoparasite communities of two *Microcebus* É. Geoffroy species (Klein et al., 2018) reported the presence of trombiculid larvae on both *M. murinus* and *M. ravelobensis* (Zimmermann, Cepok, Rakotoarison, Zietemann & Radespiel) at the same locality in Ankarafantsika National Park, but the mites were not identified. The second species is a recently described lemur that occurs sympatrically with *M. murinus* (see Zimmermann et al., 1998). Therefore, it is expected to be parasitised by the same species of trombiculids, since these mites, which are parasites in the larval stage only, are more habitat-, than host-specific (Kudryashova, 1998).

Legends to figures

Figs. 1–7 *Schoutedenichia microcebi* n. sp., larva. 1, Scutum and eyes of holotype (one sensillum missing); 2, Arrangement of dorsal idiosomal setae of holotype; 3, Arrangement of ventral idiosomal setae of holotype; 4, Dorsal idiosomal seta of holotype; 5, Ventral preanal idiosomal seta of holotype; 6, Dorsal aspect of gnathosoma of paratype ZIN 10997 (only two prongs of the palpal claw are visible); 7, Ventral aspect of gnathosoma of paratype ZIN 10997 (only two prongs of the palpal claw are visible). *Abbreviations*: AM, anteromedian scutal seta; AL, anterolateral scutal seta; Ch, cheliceral blade; Ga, galeal seta; gns, gnathocoxal seta; PC, palpal claw; H, humeral setae; PF, palpal femur; PG, palpal genu; PL, posterolateral scutal seta; PTa, palpal tarsus; PTi, palpal tibia; sens, sensillum; SB, sensillary base. *Scale-bars*: 1, 50 µm; 2, 3, 100 µm; 4–7, 20 µm

Figs. 8–11 *Schoutedenichia microcebi* n. sp., larva. 8, Holotype, dorsal aspect of idiosoma (one sensillum missing); 9, Holotype, sternal area of idiosoma; 10, Paratype ZIN 11022, scutum (sensilla missing); 11, paratype ZIN 11022, palpal claw. *Abbreviations*: AM, anteromedian scutal seta; AL, anterolateral scutal seta; D₁, dorsal idiosomal setae of 1st row; cxI, coxa I; cxII, coxa II; cxIII, coxa III; H, humeral setae; ic, infracapitulum (gnathobase); PL, posterolateral

scutal seta; sens, sensillum; SB, sensillary base; sta, anterior sternal setae; stp, posterior sternal setae; V, ventral setae. *Scale-bars*: 8, 9, 50 μm ; 10, 20 μm ; 11, 5 μm

Figs. 12–14 *Schoutedenichia microcebi* n. sp., larva paratype ZIN 10998. 12, Free part of leg I (trochanter-tarsus); 13, Free part of leg II (trochanter-tarsus); 14, Free part of leg III (trochanter-tarsus). *Abbreviations*: f₁, famulus I; f₂, famulus II; ga, genuala I; gm, genuala II; gp, genuala III; mga, microgenuala; mta, microtibiala; pST, parasubterminala; PT', pretarsala I; PT'', pretarsala II; S₁, tarsala I; S₂, tarsala II; ST, subterminala; ta, tibiala I; tm, tibiala II. *Scale-bars*: 50 μm

Figs. 15–23 *Schoutedenichia dutoiti*, larva. 15, Scutum and eyes of specimen ZIN 9974; 16, Humeral seta of specimen ZIN 9974; 17, Dorsal idiosomal seta of specimen ZIN 9974; 18, Ventral preanal idiosomal seta of specimen ZIN 9974; 19, Arrangement of dorsal idiosomal setae of holotype; 20, Arrangement of ventral idiosomal setae of holotype; 21, Dorsal aspect of gnathosoma of specimen ZIN 9970; 22, Ventral aspect of gnathosoma of specimen ZIN 9970; 23, Ventrolateral view of cheliceral blades of specimen ZIN 10214. *Abbreviations*: AM, anteromedian scutal seta; AL, anterolateral scutal seta; Ch, cheliceral blade; Ga, galeal seta; gns, gnathocoxal seta; PC, palpal claw; H, humeral setae; PF, palpal femur; PG, palpal genu; PL, posterolateral scutal seta; PTa, palpal tarsus; PTi, palpal tibia; sens, sensillum; S, palpal subterminala; S₀, palpal tarsala; SB, sensillary base. *Scale-bars*: 15, 50 μm ; 16–18, 21–23, 20 μm , 19, 20, 100 μm

Figs. 24–26 *Schoutedenichia dutoiti*, larva ZIN 10389. 24, Scutum and dorsal idiosomal setae (one sensillum missing). 25, Sternal area of idiosoma. 26, Scutum and eyes (one sensillum missing) *Abbreviations*: AM, anteromedian scutal seta; AL, anterolateral scutal seta; D₁, dorsal idiosomal setae of 1st row; cxI, coxa I; cxII, coxa II; cxIII, coxa III; H, humeral setae; ic, infracapitulum (gnathobase); PL, posterolateral scutal seta; sens, sensillum; SB, sensillary base; sta, anterior sternal setae; stp, posterior sternal setae; V, ventral setae. *Scale-bars*: 24, 25, 50 μm ; 26, 20 μm

Figs. 27–31 *Schoutedenichia dutoiti*, larva ZIN 9974. 27, Telofemur, genu, tibia, and tarsus of leg I; 28, Trochanter and basifemur of leg I; 29, Free part of leg II (trochanter-tarsus); 30, Trochanter and basifemur of leg III; 31, Telofemur, genu, tibia, and tarsus of leg III. *Abbreviations*: f₁, famulus I; f₂, famulus II; ga, genuala I; gm, genuala II; gp, genuala III; mga, microgenuala; mta, microtibiala; pST, parasubterminala; PT', pretarsala I; PT'', pretarsala II; S₁, tarsala I; S₂, tarsala II; ST, subterminala; ta, tibiala I; tm, tibiala II. *Scale-bars*: 50 μm

Cover letter

Dear Editor,

I enclose the final version of my accepted manuscript including its text corrected according to the editorial remarks and figures of high resolution (line figures at 1200 dpi and plates of photographs at 600 dpi).

Sincerely Yours,

Alexandr Stekolnikov
